

HOW TO CREATE A BUILD

OVERVIEW

Creating a build is pretty simple:

1. In the Unity Editor, select File > Build Profiles
2. Click “Build” in the bottom right: 
3. Select a new, empty folder for the build.
4. Wait for Unity to compile everything.
 - a. Sometimes this takes a while; I’ve had it take up to 20 ish minutes for the Clean World project.

TESTING THE BUILD

Before uploading the build to the main itch.io page, be sure to test it. In my experience, the first build (well, the first 10) never work. I have Node.js installed on my computer, so in case I’m the one reading this, to test it, just navigate to the build folder in the command line, run the command “http-server” and copy/paste the IP address it gives you into a browser.

For people who happen to not be me, the simplest way to test the build is to create your own private itch.io page and upload the build there to test it. See instructions in the next section for uploading the build to itch.io

UPLOADING THE BUILD TO ITCH.IO

1. Zip the folder you built the project into. It's the folder that has the index.html file inside of it.
2. Upload the zipped file to itch.
 - a. Be sure the itch project type is set to "play in browser"

IF THINGS BREAK IN THE BUILD

Tragically, things usually break a little bit in the build. I think Unity just likes taunting us. Here are a few tips that have helped me solve my build problems:

Canvas Scaling Issues

This is very common. Be sure to set all of the rebellious canvases in the Unity Editor to the UI Scale Mode of “Scale With Screen Size.” Also be sure to multiply any constant pixel values you’re using in your code by `CanvasScalerFactor.CSF.GetScaleFactor()` at run time. Beyond that, you’ll likely just have to do some fiddling with it. I’m sorry for the pain you’re about to experience.

Pesky Try/Catch blocks

I believe that in Unity web builds, try & catch blocks don’t always properly translate. So, if you have an error that is being caught by try/catch statements in the editor, it might be causing the web build to crash or malfunction. Try eliminating any try/catch statements you use in your code.

File Access Issues

When Unity builds the game, it completely throws out whatever file system you were using in the project. So accessing files with a direct file path might work in the editor, but will likely fail in the build. To solve this, you can place your files in the “Resources” folder, which Unity preserves in web builds.
